A musical note has a frequency of 440 Hz. The speed of sound in air is 330 m/s.

Part A

Wavelength

What is the wavelength of the sound?

Part B

Time period

What is the time period of the sound?

Part A

Light intensity at 12 m

The light from a bulb shines equally in all directions. If 20 W of light is given off, what will the intensity be 12 m from the lamp to 2 significant figures? (Consider the shape of the region illuminated if the light hits this surface after travelling 12 m in all directions.)

Part B

Light intensity at 24 m

What would the answer be at a distance of 24 m , to 2 significant figures?

Calculate the values indicated in the table. The speed of sound in air is 330 m s^{-1} . All phases should be given as $< 360^\circ$ and path differences should be < 1 wavelength.

Wavelength	Path difference	Phase difference	Fully constructive interference (Y/N)	Fully destructive interference (Y/N)
320 mm	160 mm	(a)	(b)	(c)

Part A Phase difference

a) What is the phase difference in degrees?

Part B Fully constructive interference

b) Fully constructive interference?

☐ Yes

☐ No

Part C Fully destructive interference

c) Fully destructive interference?

☐ Yes

☐ No

Path Difference 8

A Level

Essential Pre-Uni Physics D3.8

Two speakers are set up 13.5 m apart in an auditorium, pointing at each other. A pure sound of frequency 256 Hz is being played through them. You may assume that the phase difference of the signals as they arrive at the speakers is 0° . A person is standing on the line joining the speakers, 0.25 m from the mid point.

The speed of sound in air is 330 m s^{-1} .

Part A Phase difference

Calculate the phase difference as it would be detected by the person.

Part B Silence

The person moves to the mid point between the speakers (where the sound is loudest due to constructive interference), and then walks towards one speaker until the sound waves cancel out. How far do they walk until they find this point of near silence?

Path Difference 7

Essential Pre-Uni Physics D3.7

A Level

Two aerials are 2.50 m apart, and both are receiving the same radio signal with a frequency of 125 MHz. The phase difference between them is measured as 114° .

Part A Path difference between aerials

Calculate the path difference between the two aerials.

Part B Bearing of the transmitter from the aerials

The aerial which receives the radio signal first is directly North of the one which receives the signal slightly later. What are the possible bearings of the transmitter from the receiving aerials? You may assume that the transmitter is many kilometres from the receiving aerials, and therefore that the paths of the waves travelling to the two receivers are effectively parallel when measured in the vicinity of the receiving aerials.

Enter one of the possible bearings in the answer box below. Give your answer to 3 significant figures.
