Virus Structure and Types

Part A Structure		
Viruses are acellular (nonc	ellular) microbes that are much	than cells. They are not classed as
living organisms because the reproduction.	hey do not have their own I	Because of this, they rely on host cells for
	leic acid (either DNA or RNA) surrounde have more complex structures e.g. the	ed by a protein coat (also called a human immunodeficiency virus (HIV) is
surrounded by a	outside the protein coat). The outer la	ayer of a virus contains (), which
enable the virus to bind to	(and enter) a specific host cell.

<u>Home</u> <u>Gameboard</u> Biology Cell Biology Viruses Viral Reproduction

Viral Reproduction

One of the best-studied viruses is the lambda phage, a bacteriophage which infects *E. coli*. This virus can replicate through either the lytic cycle or the lysogenic cycle.

Part A The lytic cycle of the lambda phage

Drag the steps below (on the left) into the correct chronological order of the lytic cycle (on the right).

Available items

The virus attaches to the host cell membrane.

The virus takes over the cell machinery. Viral DNA is transcribed to produce viral mRNA, which is translated to produce viral proteins (including the protein coat of each virus). The viral DNA is also replicated to produce more copies.

The copies of viral DNA and the viral proteins assemble to produce new viruses.

The virus injects its DNA into the host cell.

The viruses cause lysis of the cell membrane, which releases the viruses out into the cell's environment, where they can infect other cells.

Part B The lysogenic cycle of the lambda phage

Drag the steps below (on the left) into the correct chronological order of the lysogenic cycle (on the right).

Available items

If one of the host cells undergoes some kind of stress (e.g. starvation), the viral DNA in its genome is transcribed and translated to produce new viruses (i.e. the virus re-enters the lytic cycle).

When the host cell replicates its genome and divides, the viral genome is replicated with it.

The virus injects its DNA into the host cell.

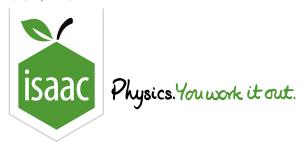

The virus attaches to the host cell membrane.

The viral DNA is integrated into the DNA of the host cell, but is not transcribed and translated to produce new viruses. This is a form of viral latency.

Retroviruses

Part A The definition
What is the definition of a retrovirus?
A virus that has an RNA genome instead of a DNA genome.
A virus that inserts a DNA copy of its RNA genome into the genome of its host cell.
A virus that has a DNA genome instead of an RNA genome.
A virus that inserts an RNA copy of its DNA genome into the genome of the host cell.
Part B The enzyme
What is the name of the enzyme that retroviruses use to make DNA?

Part C An exampl	e
------------------	---

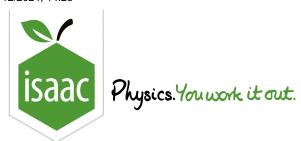

Ebola virus SARS-Cov-2 Lambda phage E. coli Tobacco mosaic virus Part D Fill in the blanks! After a retrovirus has made a copy of its genome (through the process of), this copy is inserted into the host cell's genome, and is now called a If this copy is not transcribed, then no new viruses are produced. This is known as viral This period may last years before the virus is reactivated and new viruses are produced. Items: provirus previrus transcription DNA lysis reverse transcription latency RNA	Which of these is an example of a retrovirus?
SARS-Cov-2 Lambda phage E. coli Tobacco mosaic virus Part D Fill in the blanks! Cell or Virus?

Part A What is it?

The table below gives information about different biological entities. Match the biological entity to the correct row.

Row	Contains	Does not contain	Identity
1	cell wall, ribosomes	nucleus	
2	mitochondria, central vacuole, cellulose cell wall	chloroplasts	
3	DNA, proteins	ribosomes, phospholipid membrane	
4	phospholipid membrane	cell wall, nucleus, nucleoid	
5	mitochondria, nucleus, chloroplasts	flagellum	
6	nucleus	cell wall	

Items:

(human white blood cell) (bacterial cell) (virus) (human red blood cell) (plant leaf palisade cell) (plant root cell

<u>Home</u> <u>Gameboard</u> Biology Cell Biology Viruses Virus vs Host Cell Comparisons

Virus vs Host Cell Comparisons

SARS-CoV-2, the virus that causes COVID-19, infects a particular type of human cell called type II pneumocytes, which are found in the alveoli.

Answer the questions below to compare the virus to its host cell.

Part A Volume
The SARS-CoV-2 virus is spherical and has a diameter of $100\mathrm{nm}$.
A type II pneumocyte is approximately cube-shaped and has a length of $9\mu\mathrm{m}$.
How many times larger is the volume of the host cell than the volume of the virus? Give your answer to 1 sf.
times larger.
Part B Genome length
The SARS-CoV-2 virus has a single-stranded RNA genome that is approximately 30000 bases long.
A type II pneumocyte, like all other diploid human cells, has a genome that is approximately $6 imes 10^9$ base
pairs long.
How many times longer is the genome of the host cell than the genome of the virus?

Part C Replication rate

An infected type II pneumocyte may produce up to 1000 copies of the SARS-CoV-2 virus over $10\,\mathrm{hours}$.

How much longer would it take a type II pneumocyte to give rise to 1000 cells than to produce 1000 copies of of the virus, if each type II pneumocyte can only divide once every $24 \, \mathrm{hours}$?

Assume that no cell death occurs.	
Give your answer to 2 sf.	
times longer.
