Electrochemistry Introduction

In electrochemistry, a potential difference between two half-cells is set up by having different redox couples and/or different concentrations of a given redox couple present.

Introduction Part A The potential of the side half-cell is measured relative to the side one, so the cell potential is given by subtracting the reduction potential of the side from the reduction potential of side. Standard reduction potentials can be tabulated, which correspond to values recorded the electrode. The conventional cell reaction under standard conditions against the standard consists of the right-hand side (which can be thought of as and the left-hand side subtracting the left-hand side), making sure that the number of electrons (n) transferred is the same for both sides. Items: oxidation right-hand left-hand silver hydrogen reduction platinum oxygen

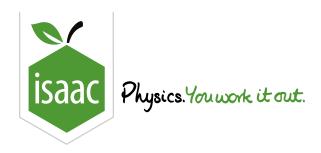

Part B Linking equations

Working out cell potentials can be useful in itself, but as a result of connections to other thermodynamic quantities, tabulated standard reduction potentials allow us to calculate, for example, equilibrium constants even of non-redox reactions or processes such as a salt dissolving.

Given that $\Delta_r G^{\circ} = -nFE^{\circ} = -RT \ln K$, rearrange the equation for K (the equilibrium constant) as a function of n (the number of electrons transferred), F (the Faraday constant), E° (the standard cell potential, for which you should use E^o in your expression), R (the universal gas constant) and T (the temperature).

The following symbols may be useful: E^o, F, K, R, T, e, ln(), log(), n

Home Gameboard Chemistry Physical Electrochemistry Combining Potentials

Combining Potentials

When half-cell potentials are combined to form a cell potential, the process is relatively straightforward: we balance the two half-equations to include the same number of electrons, and subtract the left-hand half-cell potential from the right-hand half-cell potential.

When two half-cell potentials need to be combined to instead form another half-cell potential, for a third half-reaction, the process is a little more complicated.

 $A^{(n_1+n_2)+} + n_1 e^- \longrightarrow A^{n_2+}$ has a half-cell potential of x and $A^{n_2+} + n_2 e^- \longrightarrow A$ has a half-cell potential of y.

Derive an expression for the half-cell potential of the following reaction:

$$A^{(n_1+n_2)+}+(n_1+n_2)e^- {\:\longrightarrow\:} A$$

The following symbols may be useful: n_1, n_2, x, y
