

Translation Overview

Subject & topics: Biology | Genetics | Translation Stage & difficulty: A Level P1

Part A Initiation
Translation is initiated when a binds to the end of the mature messenger RNA
(mRNA), and moves along the mRNA. When it reaches the (AUG), it facilitates the binding of the that contains the complementary
Items:
[3'] [5'] [anticodon] [transfer RNA (tRNA)] [stop codon] [start codon] [codon] [ribosome]

Part B Elongation
After the binding of the first tRNA to the first (start) codon, a second tRNA binds to the second codon. The of one tRNA binds to that of the next tRNA via The ribosome then moves to the third codon, and a third tRNA binds (bringing with it the third amino acid). As this happens, the first tRNA (but not the first amino acid) detaches. This process repeats along the length of the mRNA: tRNAs bind to the mRNA, amino acids bind to each other, and then tRNAs detach. The string of amino acids is called Items: [Amino acid] [
Part C Termination
When the ribosome reaches the, it detaches from the mRNA. The is then released from the final tRNA, and undergoes folding and post-translational modifications to become a functional
Items: protein 5' cap stop codon poly(A) tail polypeptide chain anticodon

Part D

From gene to protein

Drag the steps below (left) into the correct chronological order (right).

Available items

RNA polymerase reaches the end of the gene and transcription ends. The newly-synthesised RNA strand is called messenger RNA (mRNA).

The polypeptide chain undergoes folding and post-translational modifications to become a functional, three-dimensional protein.

Transcription factors and RNA polymerase bind to the promoter region of a gene.

The ribosome moves along the mRNA strand, and transfer RNA (tRNA) molecules bind to the mRNA strand, beginning at the "start" codon (AUG). Each tRNA molecule is bound at one end to a specific amino acid, and at the other end contains a specific triplet of unbound RNA bases called an "anticodon", which binds to complementary codons.

The mRNA strand undergoes post-transcriptional modifications and is exported out of the nucleus.

RNA polymerase moves along the DNA, allowing complementary RNA nucleotides to sequentially bind to each other (through phosphodiester bonds).

A ribosome binds to the 5' end of the mature mRNA strand.

RNA polymerase causes the two DNA strands to unwind and separate.

Adjacent amino acids bind to each other via peptide bonds, forming a polypeptide chain. Once the ribosome reaches the stop codon the polypeptide chain detaches from the last tRNA molecule.

Translation vs Transcription

Subject & topics: Biology	Genetics	Translation	Stage & difficulty: A Level P1	

In the table below, identify which statements about translation and transcription are correct, and which are incorrect. Fill in every box with either a tick (correct) or a cross (incorrect).

occurs within ribosomes	
occurs within the nucleus	
free nucleotides bind as individual nucleotides	
nucleotide binding occurs in triplets	
mRNA is involved

Question deck:

Translate the Sequences

Subject & topics: Biology | Genetics | Translation Stage & difficulty: A Level C1

The table below shows the corresponding tRNA anticodon(s) for a selection of amino acids.

Amino acid	tRNA(s) (3^\prime to 5^\prime)
glutamine	GUU, GUC
glycine	$\mathrm{CCA},\mathrm{CCG},\mathrm{CCU},\mathrm{CCC}$
lysine	UUU, UUC
methionine	UAC
phenylalanine	AAA,AAG
proline	${\rm GGA, GGG, GGU, GGC}$
tyrosine	$\mathrm{AUA},\mathrm{AUG}$
valine	$\mathrm{CAA},\mathrm{CAG},\mathrm{CAU},\mathrm{CAC}$

Part A mRNA to amino acid
Using the anticodon table above, work out the amino acid sequence that would be produced from the mRNA sequence (5 $^{\prime}$ to 3 $^{\prime}$):
AUGGGGAAGUUC
Assume that the first three nucleotides correspond to the first codon.
Amino acid 1:
Amino acid 2:
Amino acid 3:
• Amino acid 4:
Items:
glutamine glycine (lysine) (methionine) (phenylalanine) (proline) (tyrosine) (valine)

Part B Sense to amino acid
Using the anticodon table above, work out the amino acid sequence that would be produced from the following sense strand DNA sequence (5 $^\prime$ to 3 $^\prime$):
ATGCAGTATCAA
Assume that the first three nucleotides correspond to the first codon.
Amino acid 1:
Amino acid 2:
• Amino acid 3:
• Amino acid 4:
Items:
glutamine glycine (lysine) (methionine) (phenylalanine) (proline) (tyrosine) (valine)

Part C Antisense to amino acid
Using the anticodon table above, work out the amino acid sequence that would be produced from the following antisense strand DNA sequence (3 $^{\prime}$ to 5 $^{\prime}$):
TACATGCACGTC
Assume that the first three nucleotides correspond to the first codon.
Amino acid 1:
Amino acid 2:
• Amino acid 3:
• Amino acid 4:
Items:
glutamine glycine (lysine) (methionine) (phenylalanine) (proline) (tyrosine) (valine)

Part D What kind of sequence is it?
The four sequences below represent four complementary sequences of different types (DNA sense strand, DNA antisense strand, mRNA, and tRNA). Match the sequence type to the sequence.
$ullet$ TGTGAAACTGCT: DNA sense strand (5 $^{\prime}$ to 3 $^{\prime}$)
• ACACUUUGACGA:
• UGUGAAACUGCU:
• ACACTTTGACGA:
Items:
$\boxed{ DNA \; antisense \; strand \; (3' \; to \; 5') } \boxed{ mRNA \; (5' \; to \; 3') } \boxed{ tRNA \; (3' \; to \; 5') }$

Question deck:

Translation Calculations

Subject & topics: Biology | Genetics | Translation Stage & difficulty: A Level C1

Part A Polypeptide length

If a section of a gene is 420 base pairs long, how many amino acids long will the encoded polypeptide be?

Assume that the first three nucleotides correspond to one codon, and that the section does not contain a stop codon (i.e. every codon is translated into an amino acid).

Part B

Translation rate

A ribosome can translate 18 bases per second. How long would it take to produce a protein that was 300 amino acids long?

Part C Alien translation

Imagine that an alien organism is found that translates its RNA using pairs of nucleotides instead of triplets.

During translation, the alien organism can use 50 possible amino acids (rather than the 20 used in life on Earth).

What is the minimum number of different types of nucleotides that would be needed to code for all of the possible amino acids?

Question deck:

Post-translational Modifications

Subject & topics: Biology | Genetics | Translation Stage & difficulty: A Level P3

Part A Types of modifications	
	n, a polypeptide chain undergoes folding to become a functional protein. Some proteins post-translational modifications. These include:
•	(the addition of a phosphate group),
•	(the addition of a carbohydrate to form a), and
•	(the addition of a lipid to form a).
ems:	
	ycoprotein phosphorylation glycosylation proteolipid

Part B Modification locations
Proteins that will be secreted from the cell are translated in ribosomes. They then under post-translational modifications in the endoplasmic reticulum and
Proteins that will remain in the cell (i.e. will not be secreted) are translated in ribosomes.
They then undergo post-translational modifications in the
